Introduction

The purpose of this study is to analyze current flooding conditions at the EnergyPlex® Park (EPP) to be located in the area between Hobbs Industrial Air Park (HIAP) and Arkansas Junction (NM Highway 483). Figure 1 shows the location of the EPP.

Figure 1: EnergyPlex® Park location (in blue)

The EPP area consists of approximately 15 square miles covering the entire Sections 29, 30, 31, 32, 33 and the Southwest ¼ Section 34 within Township 17S 37E, Sections 1, 2 and 3 within Township 18S 36E and Sections 3, 4, 5, 6, 7, North ½ Section 8, Southwest ¼ Section 8, North ½ Section 9, and North ½ Section 10 within Township 18S 37E. Appendix A contains a map showing the EPP site and watershed with respect to the Public Land Survey System (PLSS) of New Mexico. Figure 2 depicts the area covering EPP.

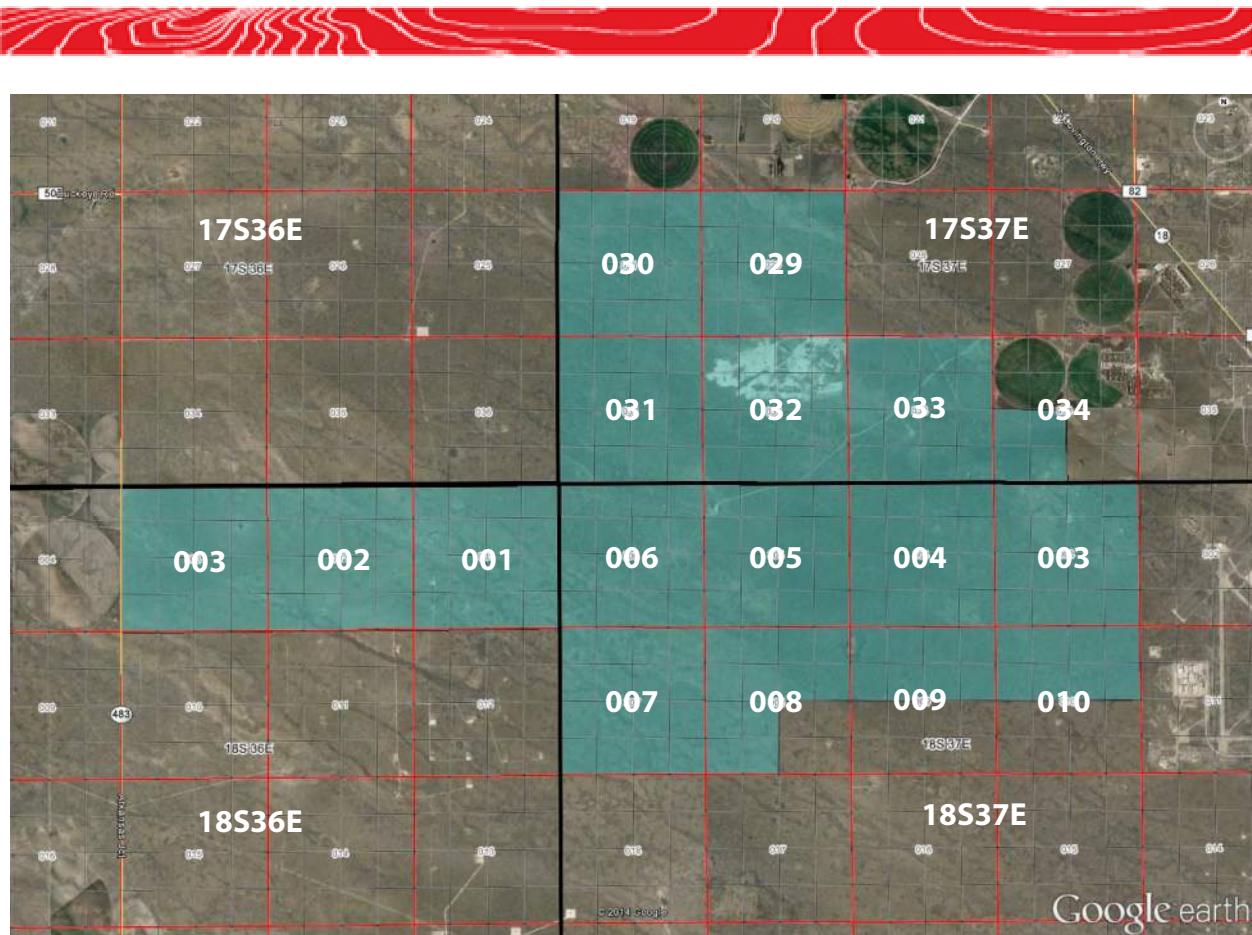

Figure 2: EPP site (in blue)

The 25 and 100-year peak runoff volumes and flow rates were determined through hydrologic analyses consistent with the methods utilized in the FEMA (Federal Emergency Management Agency) Flood Insurance Study Number 35025CV000A for Lea County, New Mexico and Corps of Engineers hydrologic modeling software HEC-HMS.

The hydraulic analysis was performed using Corps of Engineers hydraulic modeling software HEC-RAS in accordance with the criteria established by the Guidelines and Specifications for Flood Hazard Mapping Partners Appendix E: Guidance for Shallow Flooding Analyses and Mapping by FEMA April 2003. These peak flows were determined to assess the existing conditions at EPP and to establish a base flood elevation for future development that will help prevent flooding.

FEMA Flood Insurance Rate Map

The FEMA Flood Insurance Rate Map (FIRM) map number 35025C1165D with an effective date of December 16, 2008 covers approximately 320 acres within the downstream portion of the EPP site. Approximately 100 acres are designated Zone AO with a depth of 1 foot while the

remaining area is designated Zone X (unshaded). The area outside the limit of study within the EPP site is considered Zone D.

According to FEMA, the vast majority of the EPP site and watershed has not been mapped. Appendix B shows the FEMA FIRM availability at the EPP site and watershed.

Mapping

The topography of the watershed and EPP was obtained from the National Elevation Dataset (NED) produced by USGS and remote sensing method Light Detection and Ranging (LIDAR) performed at the EPP area. Appendix A contains a topographic map of the EPP site and watershed.

Watershed Delineation

The EPP site and watershed area was delineated in two separate areas. The offsite watershed encompasses the contributing area to the EPP upstream boundary. The onsite watershed encompasses the defined streams within the EPP site. The runoff flow direction is Northwest to Southeast. Figure 3 shows the extent of the EPP site and watershed.

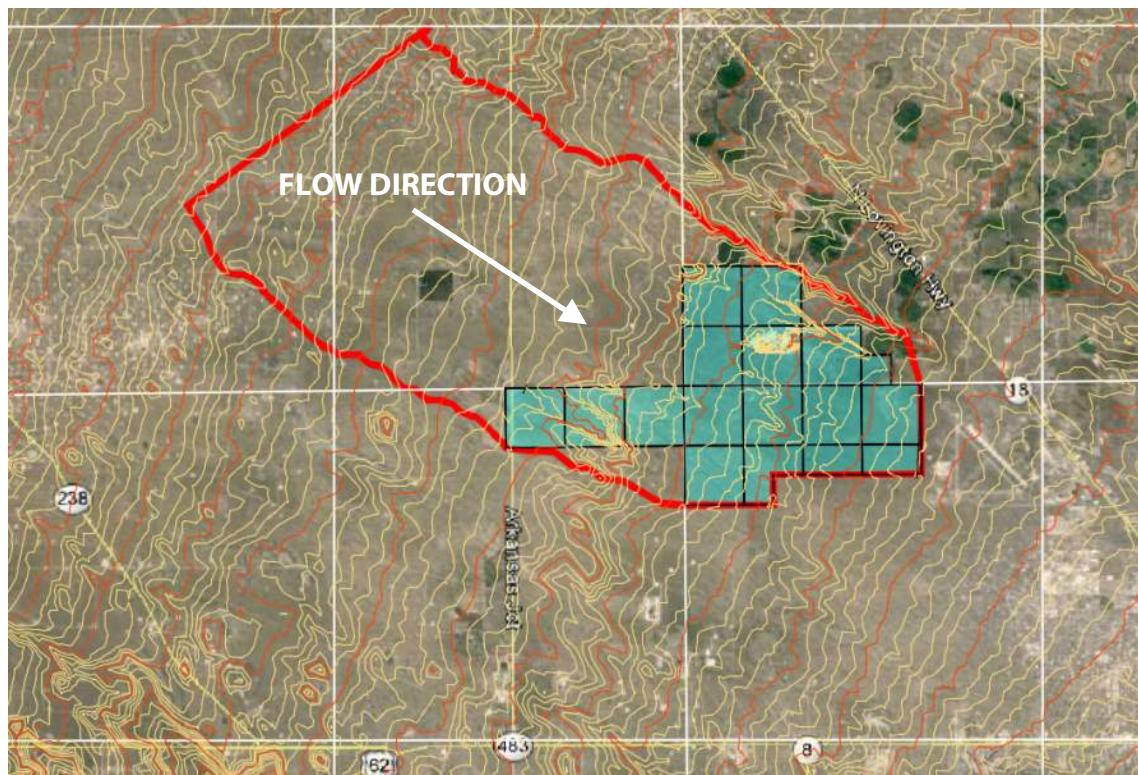

Figure 3: EPP site and Watershed

Legacy Watershed

The EPP site and watershed lies within the Monument-Seminole Draw watershed as established by United States Environmental Protection Agency (EPA). The Monument-Seminole Draw watershed covers approximately 2,650 square miles, extending from northeastern Lea County, New Mexico to central Andrews County, Texas. Figure 4 depicts the EPP area and watershed with respect to the Monument-Seminole Draw watershed as shown in the MyWATERS Mapper.

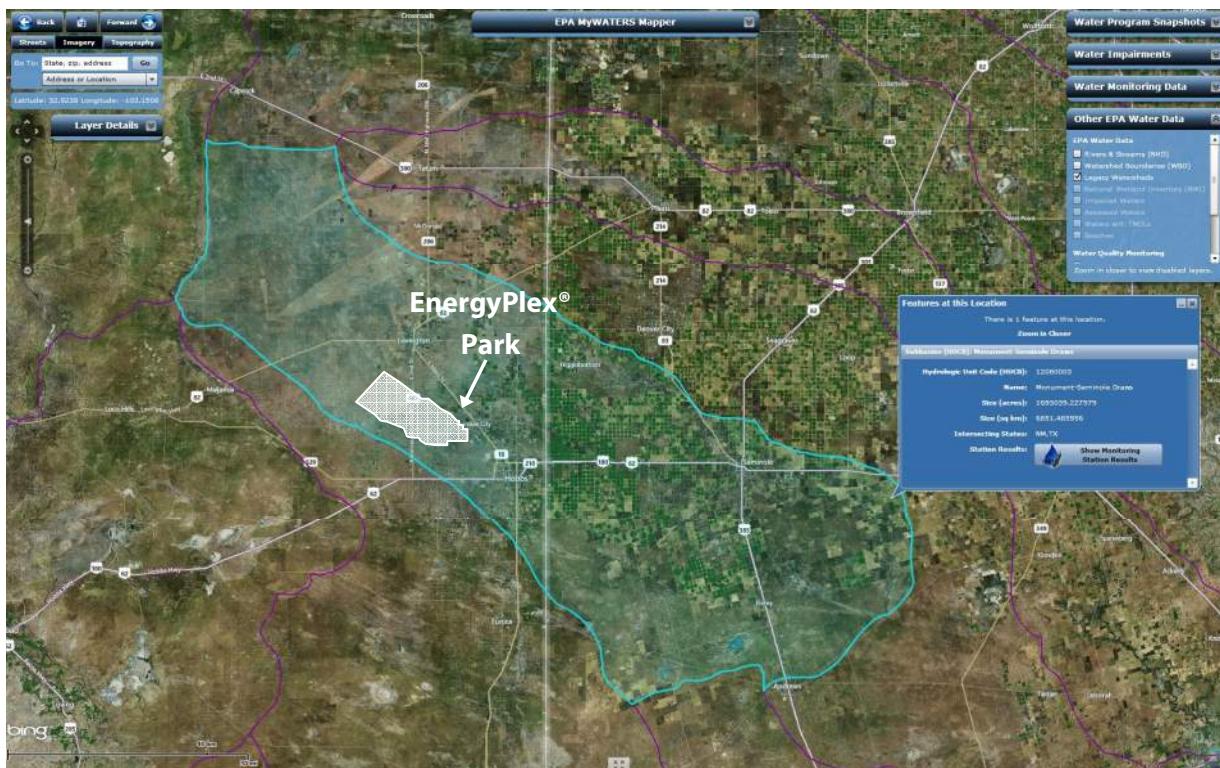

Figure 4: Monument-Seminole Draw Watershed in blue (EPA MyWATERS Mapper)

EPP Offsite Watershed

The watershed delineation is based on the criteria established by the FEMA Flood Insurance Study Number 35025CV000A for Lea County, New Mexico¹ where “the larger drainage basins that lie northwest of the City of Hobbs were found to be noncontributing beyond a length of approximately 10 miles. This is due to large amounts of channel infiltration occurring in the broad shallow channels or draws. In addition to channel infiltration, there are numerous small closed basins within the larger basins that reduce the amount of runoff. These small closed basins are called playa lakes or sinkholes. Storage in these areas was accounted in the curve number selection”.

¹ FEMA Flood Insurance Study Number 35025CV000A Lea County New Mexico, Effective Date: December 16, 2008

Offsite Subwatershed Boundaries

The EPP offsite watershed was divided into subwatersheds based on the topographic information. This subdivision allowed for determination of specific flow rates at selected locations at the upstream boundary of the EPP site. Figure 5 depicts the offsite subwatershed layout. Appendix C contains a map showing the extent and numbering of the offsite subwatersheds.

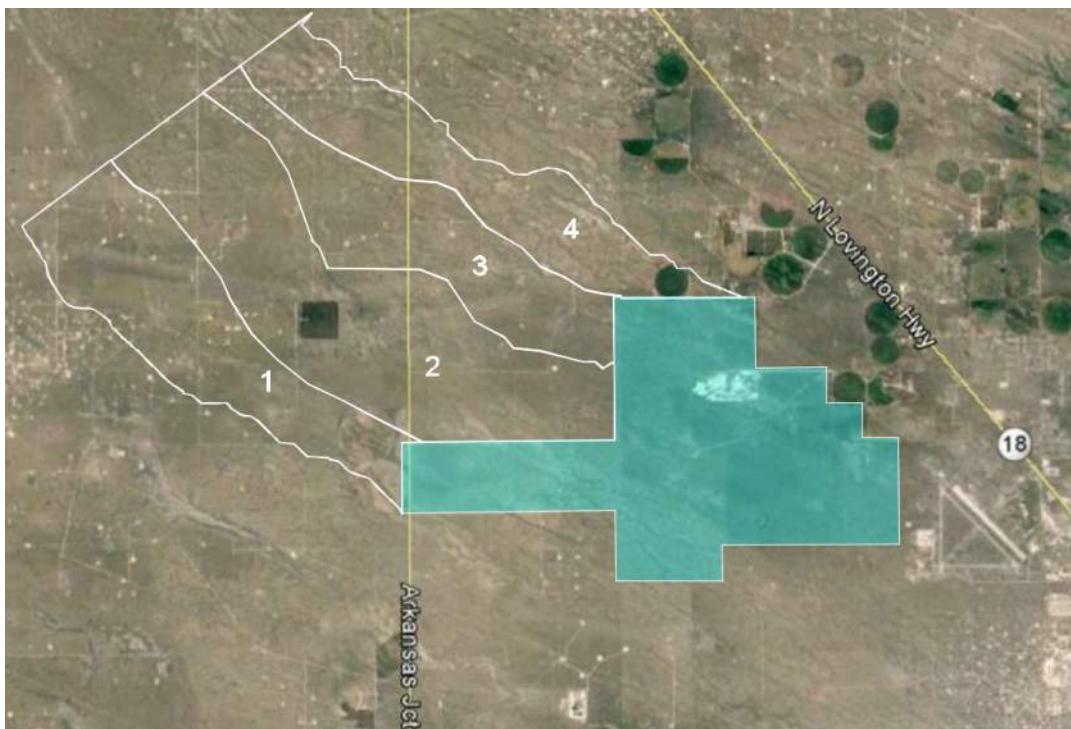

Figure 5: Offsite Subwatershed Areas

The areas corresponding to each offsite watershed are summarized in Table 1. The total area of the offsite watershed is approximately 34.3 square miles.

Table 1: EPP Offsite Subwatershed Areas

EPP OFFSITE SUBWATERSHEDS			
SUBWATERSHED	AREA (ft ²)	AREA (acres)	AREA (mi ²)
1	222,522,328	5,108	7.98
2	358,414,945	8,228	12.86
3	187,930,880	4,314	6.74
4	186,517,881	4,282	6.69
TOTAL	955,386,034	21,933	34.27

Highway 483 (Arkansas Junction) profile was analyzed to determine possible runoff diversions. At the time of this study, no hydraulic structures were found crossing the roadway

within the area. Based on this analysis, it was concluded that the highway elevation and alignment would not modify nor divert the flow path of upstream runoff. The total area of the watershed contributing to EPP was found to be 52 square miles including the EPP site.

EPP Onsite Watershed

The EPP onsite watershed was subdivided into six smaller subwatersheds. This subdivision allowed for determination of specific flow rates at the upstream and downstream boundaries of the EPP site. Appendix C contains a map showing the extent and numbering of the onsite subwatersheds. Figure 6 depicts the onsite subwatersheds layout.

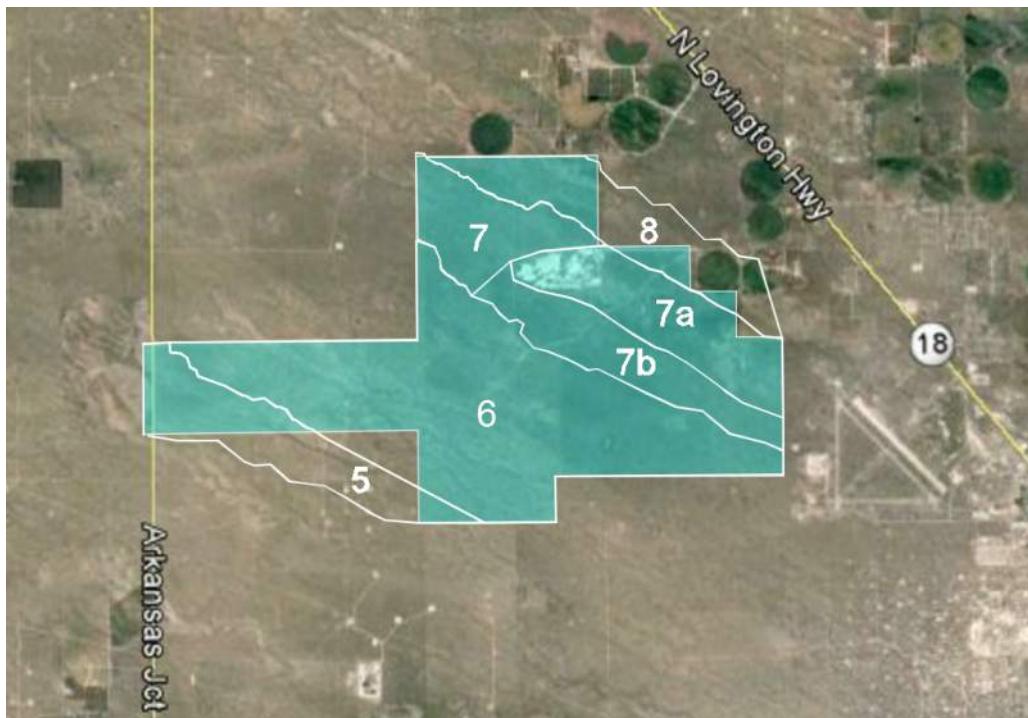

Figure 6: EPP Onsite Subwatershed boundaries

The areas corresponding to each onsite subwatershed are summarized in Table 2. The total area of the onsite watershed is approximately 14.2 square miles.

Table 2: EPP Onsite Subwatershed Areas

EPP ONSITE SUBWATERSHEDS			
SUBWATERSHED	AREA (ft ²)	AREA (acres)	AREA (mi ²)
5	60935517	1399	2.19

7b	58019540	1332	2.08
8	61819699	1419	2.22
TOTAL	489,919,380	11,247	17.57

Hydrologic Analysis

The hydrologic analysis for the watershed affecting the EPP site was performed to determine the 100-year 6-hour and 25-year 6-hour peak flow rates at the upstream and downstream boundaries of the site. The peak runoff was developed using HEC-HMS software and determined using the Soil Conservation Service (SCS) Transform Method. Engineering judgment was applied to interpret the results and select the most appropriate peak flows affecting the area.

Rainfall

Point Precipitation Frequency Estimates for New Mexico – Hobbs 13 W data from the National Oceanographic and Atmospheric Administration (NOAA) Atlas 14 were utilized in the hydrologic modeling. At this location, the rainfall for a 100-year, 6-hour storm and a 25-year, 6-hour storm was determined to be 5.30 and 4.03 inches respectively.

The frequency storm method was used in HEC-HMS as the meteorological model. This method is designed to recreate a storm event from statistical precipitation data. A 6-hour storm was selected for intensities and duration, while the frequencies were set to be 1% and 4%. The position of the peak runoff was selected at 33% of the 6 hour rainfall event. Appendix D shows the Point Precipitation Frequency Estimates for New Mexico – Hobbs 13 W data from NOAA.

Soil Data

Soil reports and hydrologic soil group classifications for the EPP offsite and onsite subwatershed areas were obtained from the USDA Web Soil Survey. The predominant hydrologic soil group was found to have moderate to slow infiltration rates.

Curve Number Selection

As established by the FEMA Flood Insurance Study² “a curve number of 55 was selected for use in the model for undeveloped areas around the City. This curve number was found by superimposing an infiltration rate curve with a rainfall hyetograph. The difference in area between these two curves produced a volume of runoff equivalent to that produced using curve number 55. Two ring infiltration tests were performed in the vicinity of the City to produce the infiltration curve used in selecting the curve number. There was little or no antecedent moisture at the time of the infiltration tests”.

² FEMA Flood Insurance Study Number 35025CV000A Lea County New Mexico, Effective Date: December 16, 2008

Based on the information provided in this study, a consistent curve number of 55 was used to perform the hydrologic analysis. The loss method selected in HEC-HMS was the SCS curve number.

Time of Concentration and Lag Time

Time of Concentration within the offsite and onsite subwatersheds was determined using the Kirpich formula. The variables required in this formula are slope and longest flow path length within a particular subwatershed.

The SCS loss method requires Lag Time as an input parameter for peak runoff calculation. Based on observations by the SCS, the Lag Time is generally 60% of the Time of Concentration. This relationship was used for the determination of the Lag Time.

Tables 3 and 4 summarize the times of concentration (TOC) and lag time calculated for the EPP offsite and onsite subwatersheds.

Table 3: EPP Offsite Subwatersheds Time of Concentration and Lag Time

EPP OFFSITE SUBWATERSHEDS							
SUBWATERSHED	AREA (acres)	LONGEST FLOW PATH (ft)	SLOPE (ft/ft)	TOC (min)	TOC (hrs)	LAG TIME (min)	LAG TIME (hrs)

8	2.22	214	6.60	48	419	6.53	106

Existing Materials Pit

The existing materials pit located at the west end of Alabama Street significantly impacts the downstream conditions of onsite subwatersheds 7a and 7b. Based on current topography, approximately 65% of the runoff accumulated at Junction 3 will route to the pit. The remaining 35% is assumed to route through onsite subwatershed 7b towards the downstream boundary of the EPP. The existing materials pit storage capacity is approximately 260 acre-feet prior to overflowing. As a result, peak discharges at Junction 5 will not experience significant contributions from offsite subwatersheds nor onsite subwatersheds immediately upstream of the pit.

EPP Downstream Boundary Runoff

The peak runoff rate for the 100-year 6-hour and 25-year 6-hour peak flow rates at the EPP downstream boundary was calculated using the SCS Unit Hydrograph Transform Method in HEC-HMS. Each junction represents the combined peak discharge of the upstream offsite subwatershed with the downstream onsite subwatershed.

Figure 8 shows a graphical representation of the HEC-HMS hydrologic model.

The peak discharges shown in Table 7 were used to perform the hydraulic modeling within the EPP site. Appendix E contains the HEC-HMS output from the hydrologic analysis.

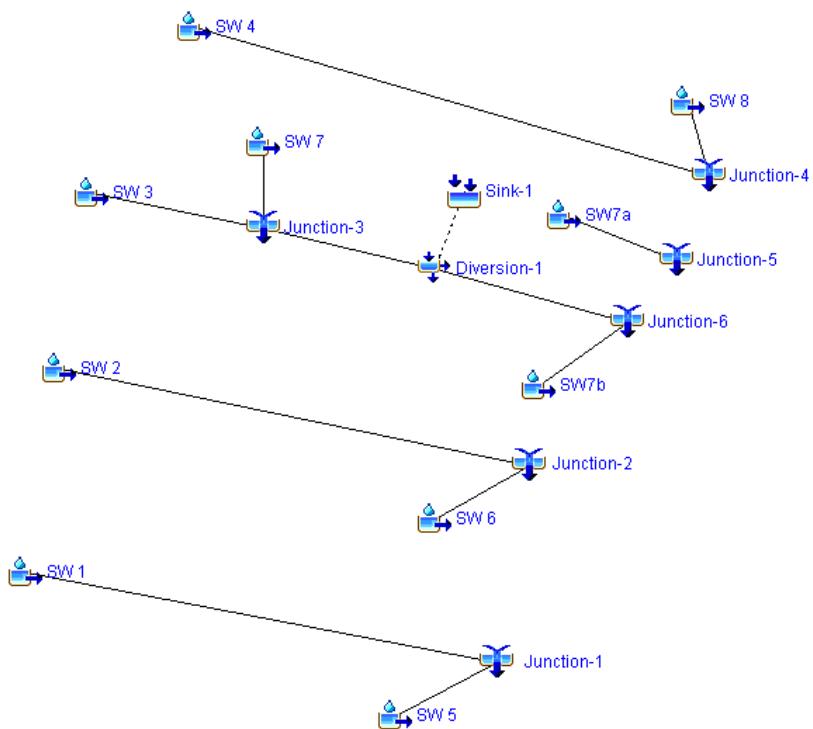

Figure 8: HEC-HMS hydrologic model layout

Hydraulic Analysis

Drainage conditions at the EPP onsite subwatersheds were analyzed in accordance with FEMA Guidelines and Specifications for Flood Hazard Mapping Partners, Appendix E: Guidance for Shallow Flooding Analyses and Mapping³. The flood elevations for a 24-year 6-hour storm and 100-year 6-hour storm return periods were determined using HEC-RAS.

Normal depth conditions and steady state flow were assumed in the hydraulic analysis. The peak discharge obtained at the EPP downstream boundary was used along the entire reach length.

The site is comprised of multiple flow paths, many of them converging and/or diverging at several locations with undefined riverbanks. Evidence of sheet flow can be found at the south and southeast portion of the EPP site. Figure 9 illustrates the amount of flow paths and high points obtained from the LiDAR contour data.

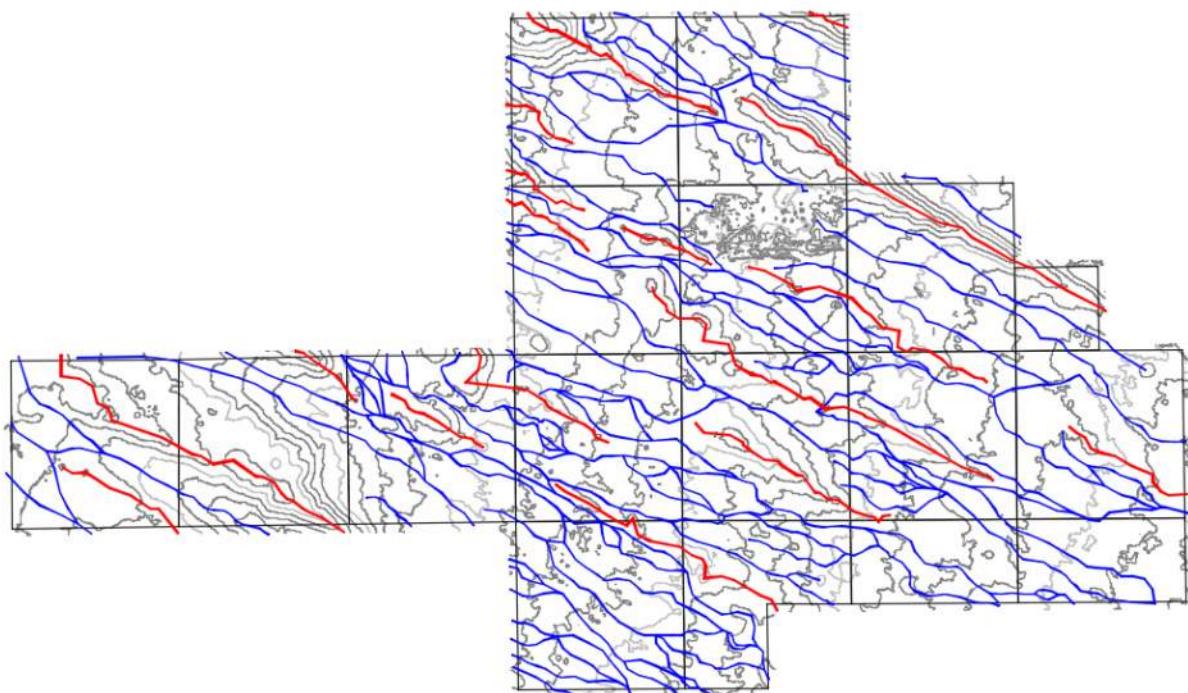

Figure 9: Identified flow paths (blue) and high points (red)

Six main reaches, one per onsite subwatershed, were used to analyze the topographic information and to extract cross sections. In order to account for areas susceptible to sheet

³ FEMA Guidelines and Specifications for Flood Hazard Mapping Partners, Appendix E: guidance for shallow flooding Analyses and Mapping, April 2003.

flow, cross sections were obtained at approximately 1,000 to 2,000 feet intervals and placed uniformly across each onsite subwatershed area.

Some cross sections within onsite subwatersheds 6, 7, 7a and 7b were skewed at selected locations to maintain uniformity of riverbank elevations. LiDAR contour data (1 foot contours) was used to obtain cross sections within onsite subwatersheds 6, 7, 7a and 7b. A combination of LiDAR and National Elevation Dataset (NED) contours (5 feet contours) were used to obtain cross sections within onsite subwatersheds 5 and 8. Cross section layouts can be found in Appendix F. Figure 10 shows the location of the six reaches used for the hydraulic analysis.

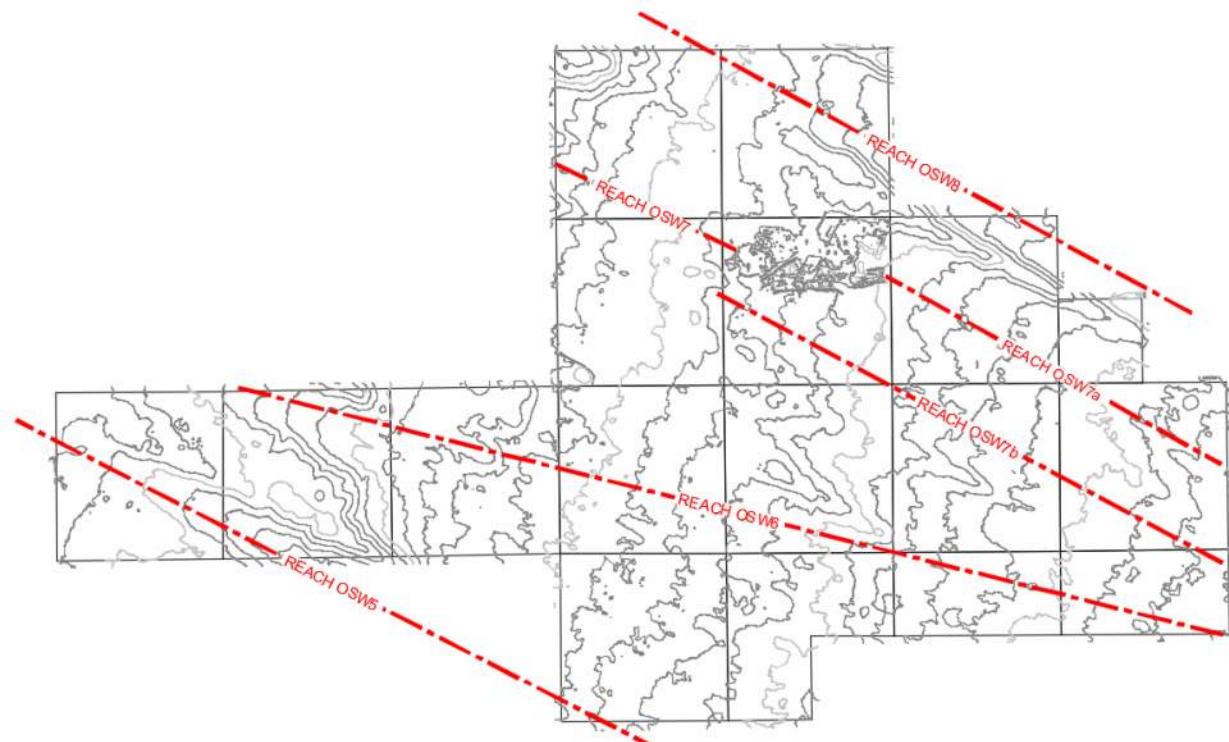

Figure 10: Six main onsite reaches

The hydraulic analysis of the cross sections was performed using a Manning's roughness coefficient of 0.050 corresponding to scattered brush and heavy weeds within a flood plain. This coefficient was maintained constant along the entire cross-section width and length.

According to FEMA Guidelines, "Generally, the average flow depth at a cross section in a shallow flooding (ZONE AO) area is obtained by dividing the flow area with the water-surface top width. A weighted average of all the average flow depths at all cross sections within a selected reach length would be used to define the extent of shallow flooding. For National Flood Insurance Program purposes, areas of shallow flooding with average depths of 1.0 foot or less are designated as Zone X".

Based on these guidelines, the flood elevations for a 24-year 6-hour storm and 100-year 6-hour storm return periods were determined. Average flow depths along reaches OSW5, OSW6, OSW7 and OSW8 were calculated below one foot and designated as Zone X (undefined).

Results from the HEC-RAS analysis are shown in Appendix G. Appendix H contains wetted boundary maps for a 25-year 6-hour storm and a 100-year 6-hour storm.

Conclusions and Recommendations

According to FEMA FIRM zones⁴, areas of moderate to low risk are defined as:

- **Zone B and X (shaded)** Area of moderate flood hazard, usually the area between the limits of the 100-year and 500-year floods. B Zones are also used to designate base floodplains of lesser hazards, such as areas protected by levees from 100-year flood, or shallow flooding areas with average depths of less than one foot or drainage areas less than 1 square mile.
- **Zone C and X (unshaded)** Area of minimal flood hazard, usually depicted on FIRMs as above the 500-year flood level. Zone C may have ponding and local drainage problems that don't warrant a detailed study or designation as base floodplain. Zone X is the area determined to be outside the 500-year flood and protected by levee from 100-year flood.

Under current conditions, the EnergyPlex® Park was designated as Zone X with moderate to low risk of flooding. Since the 500-year flood was not analyzed in this report, the flood risk within the designated Zone X areas are either moderate or low and remains undefined.

Pettigrew & Associates recommends the establishment of finished floor elevations at 18 inches (minimum) above the 100-year flood water surface elevation determined at the nearest cross section.

Limitations

The results provided within this report consist of opinions and conclusions of the consulting engineer. The only warranty or guarantee made by the engineer, in connection with this report, is that the analyses contained herein are performed with the care and skill ordinarily exercised by members of the same profession practicing under similar circumstances, at the

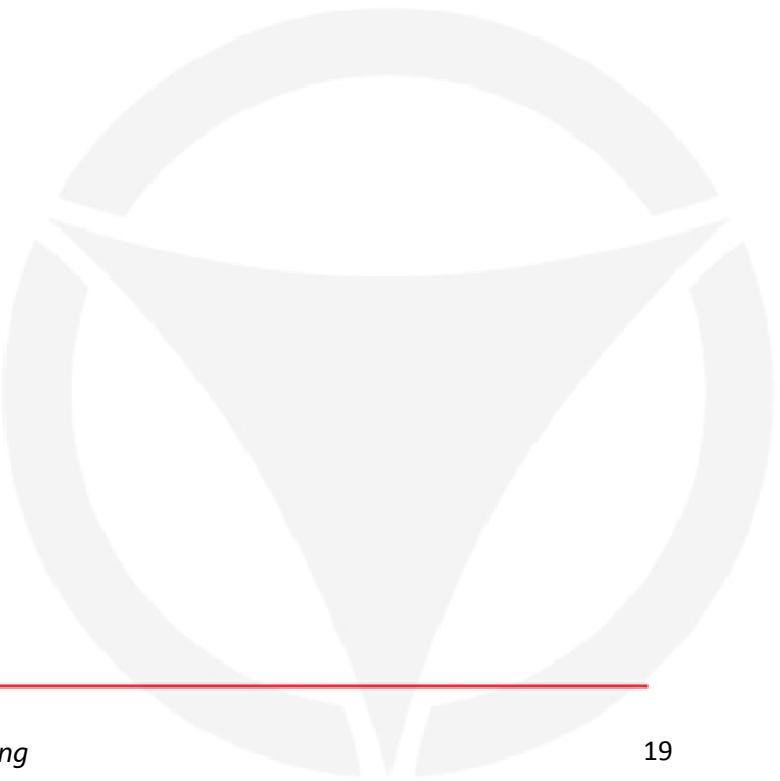

⁴ FEMA Managing Floodplain Development Through the NFIP, Unit 3 NFIP Flood Studies and Maps. March 5, 2007

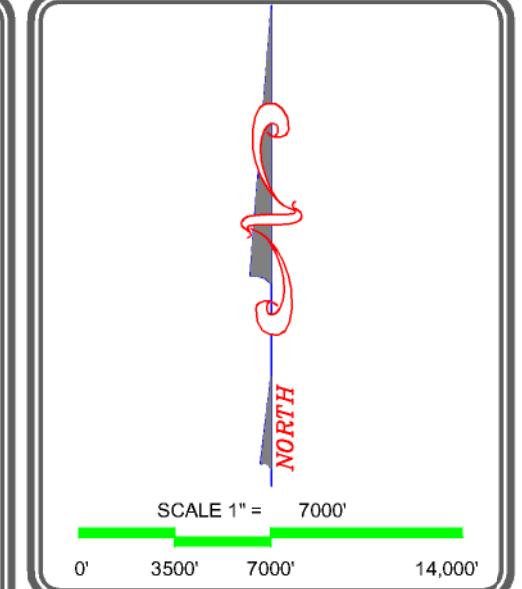

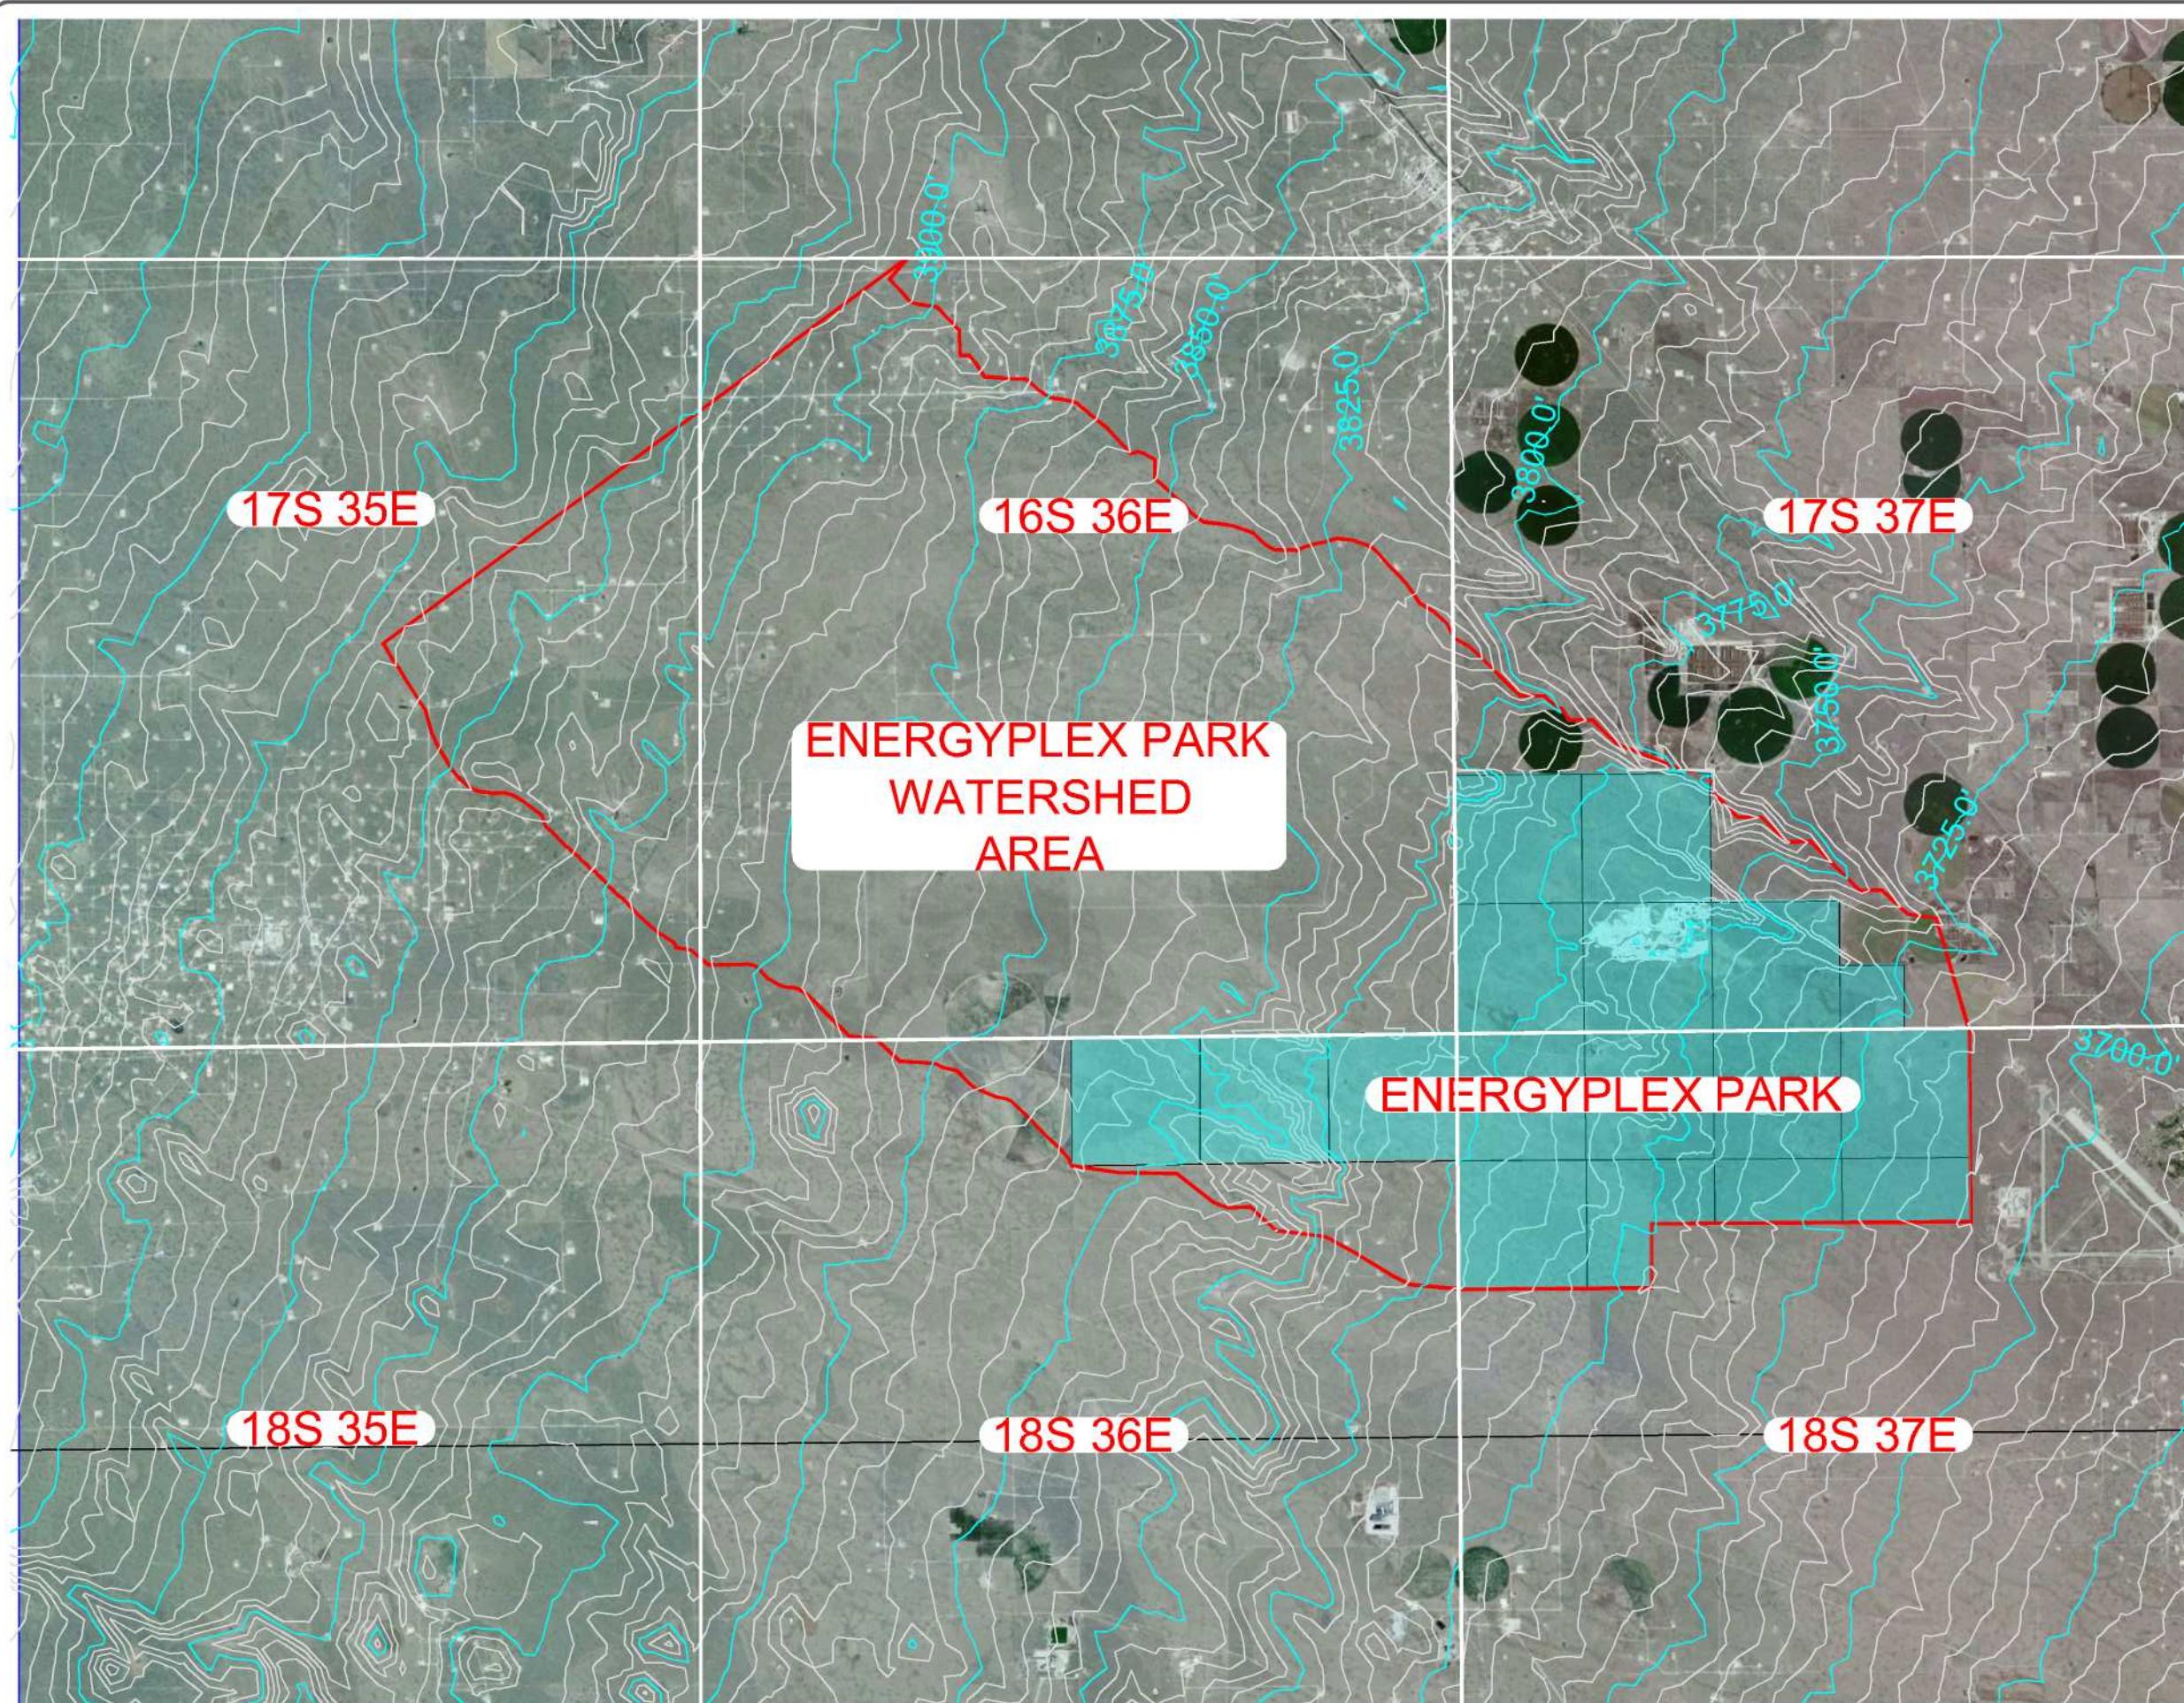

same time, and in the same or similar locality. No other warranty, expressed or implied, is made or intended to be made by submitting this report. Any deviation or adjustment to or from the above recommendations or any change in site conditions or intended development of the project may nullify the conclusions of this report.

¹ Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS). Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.

Estimates from the table in csv format:
